Development of a Motor Unit Number Estimation Technique in Normal Dogs Laura Vasquez,2011 Motor unit number estimation MUNE is an electrophysiologic technique for quantifying the lower motor neuron LMN system MUNE has proven useful in evaluating and monitoring neurodegenerative diseases such as amyotrophic lateral sclerosis ALS Recently a missense mutation in the canine superoxide dismutase 1 SOD1 gene has been shown to be a risk factor for canine degenerative myelopathy DM suggesting homology to familial SOD1 ALS To date the LMN component of DM has not been well characterized or quantified The modified incremental stimulation MUNE technique was applied to the sciatic deep peroneal nerve branch with bilateral recordings at the extensor digitorum brevis muscle of 17 clinically normal dogs Mean SD value for the entire MUNE pool was 51 21 with a range from 8 to 154 No statistically significant difference was noted between pelvic limbs P 0 14 or between different age groups 7years old or 7 years old P 0 17 Test retest reliability was assessed for trials performed under different anesthetic episodes intermittent versus trials performed under the same anesthetic episode consecutive The intraclass correlation coefficients for consecutive and intermittent MUNE evaluations were 0 73 and 0 65 respectively These results provide preliminary reference ranges for normal dogs and document the potential utility of EDB modified incremental stimulation MUNE for longitudinal monitoring of lower motor neuron loss in DM affected dogs

Motor Unit Characterization in Canine Degenerative Myelopathy Brandie Morgan, 2013 Dogs homozygous for missense mutations in superoxide dismutase 1 SOD1 develop a late onset neuromuscular disorder called degenerative myelopathy DM that has many similarities to amyotrophic lateral sclerosis ALS Both disorders are characterized by widespread progressive declines in motor and sensory functions accompanied by atrophic changes in the ascending and descending spinal cord tracts Additionally some forms of ALS are also associated with SOD1 mutations In end stage ALS death usually occurs as a result of respiratory failure due to severe functional impairment of respiratory muscles The mechanisms that lead to this loss of function are not known Dogs with DM are euthanized at all stages of disease progression providing an opportunity to characterize the onset and progression of any pathological changes in the respiratory muscles that may precede respiratory failure To characterize such potential disease related pathology we evaluated intercostal muscles from Boxer and Pembroke Welsh Corgi PWC dogs that were euthanized at various stages of DM disease progression DM was found to result in intercostal muscle atrophy fibrosis and an alteration in muscle fiber type composition This pathology was not accompanied by retraction of the motor axon terminals from the muscle acetylcholine receptor complexes suggesting that the muscle atrophy did not result from physical denervation To determine if other components of the thoracic motor unit cell body axon and myofibers also demonstrated morphological changes consistent with dysfunction histopathologic and morphometric analyses were conducted on thoracic spinal motor neurons MNs and in motor root axons from DM dogs Because sensory dysfunction is known to occur in DM dorsal root ganglia DRG and sensory root axons were also analyzed No alterations in MNs or motor root axons were observed in either breed However advanced stage PWCs exhibited significant losses of sensory root axons and numerous DRG sensory neurons displayed evidence of degeneration These results indicate that intercostal muscle atrophy in DM is not preceded by physical loss of the MNs innervating these muscles or of their axons Axonal loss in thoracic sensory roots and sensory nerve death suggest sensory involvement may play an important role in DM disease progression Results from this investigation support previous findings that DM is a multisystem disease with many similarities to human familial SOD1 D90A ALS indicating that DM is a suitable disease model for this form of ALS Further analysis of the mechanisms responsible for these morphological findings would aid in the development of therapeutic intervention for both diseases

Quantitative Assessment of HSP70, IL-1 β and TNF- α in Spinal Fluid and Spinal Cord Sections of Dogs with Histopathologically Confirmed Degenerative Myelopathy and Control Dogs Mathew Collin Lovett, 2013 Abstract Pro inflammatory cytokines such as IL 1 and TNF α appear to play important roles in autoinflammation associated with amyotrophic lateral sclerosis ALS but underlying cellular mechanisms related to this process remain to be fully defined Canine Degenerative myelopathy DM is a spontaneous large animal model of familial ALS of man and represents a valuable tool through which to evaluate the role of these pro inflammatory cytokines in the neurodegenerative process Here we quantify the expression of IL 1 and TNF α in conjunction with hsp70 another potent stimulator of the innate immune response in cerebrospinal fluid CSF and spinal cord sections from control dogs and dogs with histopathologically confirmed DM Concentrations of hsp70 IL 1 and TNF α in CSF were determined using high sensitivity ELISA and protein expression in various regions of the spinal cord was determined by immunohistochemical staining IHC and quantified using Aperio Scanscope Aperio Technologies Vista CA Concentrations of all three proteins were below the limit of assay detection in CSF for both normal n 10 and DM affected dogs n 10 Tissue analysis of IHC staining revealed enhanced hsp70 expression in ependymal cells of dogs with DM compared to controls p 0.003 IL 1 and TNF α staining was reduced in white matter of DM affected dogs likely artifactual due to negative staining created by the pathology associated with DM Based on these findings hsp70 could serve as an important biomarker or trigger for sustained inflammation in DM and ALS and further research in this area is warranted

Molecular Genetic Studies in Canine Inherited Diseases Including Neonatal Cerebellar Ataxia, Degenerative Myelopathy and Multiple System Degeneration Rong Zeng, 2013 The inherited diseases of the domestic dog mimic a wide spectrum of common human disorders By identifying the genes that harbor the mutations underlying dog diseases we not only provide powerful diagnostic DNA tests for dog breeders their veterinarians and but also provide spontaneously occurring canine models for human diseases Since the first high quality dog genome reference sequence was published and made publically accessible various molecular strategies have been applied in the canine genetic studies including candidate gene analysis linkage analysis and genome wide allele association studies Most recently our lab has focused on the discovery of causal sequence variants in the next generation whole genome sequences of individual affected dogs This has enabled us to identify disease causing genes in dogs with relevance for human health We describe here the identification of causative mutations for three different canine diseases neonatal cerebellar ataxia canine degenerative myelopathy and canine multiple system degeneration In addition we discuss the potential importance of these canine diseases if used as human disease models
